

Lecture 09 Summary

- Mutability (from L08)
- Navigability
- Class Variables
- Class Methods

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

1

By the end of this lecture, you will be able to distinguish between *mutable* and *immutable* classes.

You will also be able to describe the *navigability* of an object model.

You will also be able to create *unidirectional* and *bidirectional* associations between objects.

You will also be able to create classes with *class variables* and *class methods*.

2

Mutability Summary

- Things to check:
 - Are all of the instance variables private?
 - Do any public methods change the instance variables?
 - Do any of the getters return a reference to a mutable instance variable?

3

Navigability

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

4

Consider the object model

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

5

Exercise

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

6

Navigability in OO Languages

- Object-oriented (OO) languages support *unidirectional* associations (e.g., has-a)

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

7

Example

Car.java:

```
public class Car
{
    ... attributes of car ...
}
```

Driver.java:

```
public class Driver
{
    private Car car;
    ... other attributes of driver ...

    public void setCar(Car aCar)
    {
        car = aCar;
    }
}
```

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

8

How could we achieve a bidirectional association between Driver and Car?

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

9

Possibilities

What we want

What we don't want

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

10

Draw the object model and describe the navigability...

Customer.java:

```
public class Customer
{
    private Transaction[] transactions;
}
```

BankAccount.java:

```
public class BankAccount
{
    private Customer customer;
}
```

Transaction.java:

```
public class Transaction
{
    private BankAccount bankAccount;
}
```

Analysis:

- What would these methods look like:
 - addTransaction,
 - setBankAccount, and
 - setCustomer?
- Describe a simpler design

Navigability Summary

- OO Languages only *directly* support unidirectional associations
- Bidirectional associations (that ensure consistency) require extra work
- Result: object model less navigable
- Design question: *which object is likely to require information from the other object?*

13

Class Variables and Class Methods

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

14

Example

```
public class SquareRootProgram
{
    public static void main(String[] args)
    {
        if (args.length != 1)
        {
            System.out.println("Too few arguments");
        }

        double arg = Double.parseDouble(args[0]);
        double root = Math.sqrt(arg);

        System.out.println("The square root is: " + root);
    }
}
```

Example

- What are “Math”, “Double”, and “System”?
- Do we have any instances of a “Math” object?
- <http://java.sun.com/javase/6/docs/api/>

Class Variables

- Variables that are associated with a particular *class*.
- Can think of as: variables that are the same for all instances.

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

17

Example

```
public class Customer
{
    private static int numInstances = 0;

    ... instance variables ...

    public Customer()
    {
        numInstances++;
        ... other initialization code ...
    }

    ... instance methods ...
}
```

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

18

Class Method

- Methods that are associated with a particular *class*.
- Can think of as: methods that do not require knowledge about any particular instance.

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

19

Example

```
public class Customer
{
    private static int numInstances = 0;

    public Customer()
    {
        numInstances++;
    }

    public static int getNumInstances()
    {
        return numInstances;
    }
}
```

February 9, 2009

Slides by Mark Hancock
(adapted from notes by Craig Schock)

20

Example: Constants

```
public class Mole
{
    public static final float AVAGADRO_CONSTANT = 6.02E+23f;
    ...
}
```

(adapted from notes by Craig Schock)

21

Summary

- Class variables and class methods are associated with a particular *class*, but not to any particular *instance* of that class.
- The `static` keyword indicates a class variable or method.
- The `final` keyword indicates that something is unchangeable
