Java I/O Summary

- File class
 - Is a name for information on the hard disk
 - Can use this class to create, delete, list files, etc.
- Scanner class
 - Simple class for reading text from a file
- Byte Streams & Character Streams
- Filter Streams

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

.

By the end of this lecture, you will be able to use the File class and Scanner class to read data from text files in your programs.

You will also be able to use byte & character streams to read and write data using different encodings.

You will also be able to read and write objects to/from a file.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

-

When your program ends, what happens to all of the information you had in memory?

When your computer shuts down, what happens to all of your work (e.g., documents, music, photos, etc.)?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

3

Where does the information get stored:

- a) when you run your program
- b) when you turn off your computer?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

File

- Most operating systems use the metaphor of a file to represent stored information.
- Files are usually stored in a hierarchy within the operating system.
- A file is just a name that any program can use to access a particular part of the hard disk.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

5

File class

- In Java, there is a class that encapsulates the information about a particular file on the hard disk and lets you do operations on that file.
- Exercise: look at the File class in the Java API

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Exercise: create a program that lists all of the files in the directory named "Documents".

String[] list()

Returns an array of strings naming the files and directories in the directory denoted by this abstract pathname.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

7

When your favourite music player (e.g., iTunes) plays an mp3 file, how does it get the information that it contains?

Where does it put the information?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Scanner

• The Scanner class is one of the simplest ways in Java to read textual data from a file.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

C

Scanner

- Two constructors you can already use:
 - one takes a File
 - one takes a String
- Methods:
 - hasNext()
 - next(), nextInt(), nextFloat(), etc.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Did anyone look at the getFile method provided in Assignment #3?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

11

In A3Helper.java...

Exercise: create a program that reads a list of floating-point numbers from a file called "numbers.txt" into a LinkedList.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

13

In what form is the information in "numbers.txt" stored on the computer?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Streams

- A series of bytes that we can read or write
- Reading
 - can read each byte from left to write
 - can read until we reach the end of the stream
- Writing
 - bytes stored in the order they are written
 - can write until the operating system stops us
- Can do both at the same time (but it requires special functionality)

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

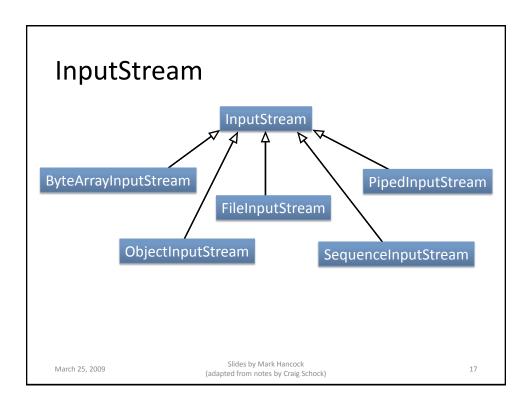

15

Byte Streams

- The unit being read or written is a byte
- Two important parent classes:
 - InputStream
 - OutputStream

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

InputStream methods

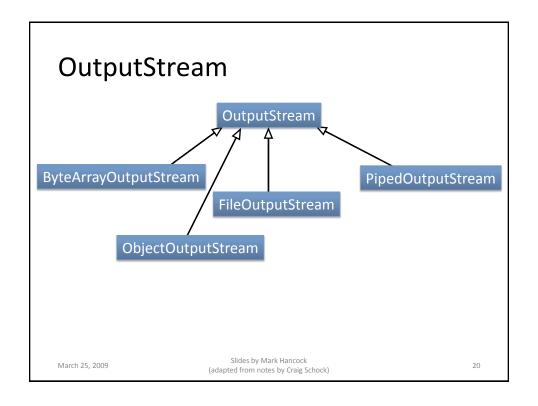

March 25, 2009

Method	Description
int read()	Reads a single character, returns as an integer
int read(byte[] buffer)	Reads bytes from stream and places them into the buffer. The maximum number of bytes read will be equal to the size of the buffer. This method returns the number of bytes read
int read(byte[] buffer, int offset, int length)	Reads up to length bytes and places them into the buffer at location buffer[offset]. This method returns the number of bytes read
int available()	The number of bytes which can be read without blocking
long skip (long n)	This method skips over n bytes in the stream
close()	Closes the stream and releases any system resouces associated with the stream
boolean markSupported()	Returns true if this stream supports the mark and reset methods
mark (int readlimit)	Marks the current location within the stream. The readlimit parameter indicates how many bytes can be read before the mark becomes invalidated
reset()	Repositions the stream to the location set with the last call to mark.

Slides by Mark Hancock (adapted from notes by Craig Schock)

InputStream subclasses

Class	Description
ByteArrayInputStream	The constructor for this class is provided with a byte array. This byte array contains the bytes which will be provided by the stream. This class is useful if the programmer wishes to access a byte array using the stream interface (i.e. reading sequential bytes)
ObjectInputStream	This class takes another InputStream as a constructor parameter. It reads bytes from the input stream and interprets them as <i>Serialized Objects</i> (which is covered in more detail later).
SequenceInputStream	Constructor takes multiple InputStreams and allows logical concatenation of the streams. When one stream ends, reading continues from the next, and so on. The program is unaware that the stream from which data is being read changes.
FileInputStream	This is the most commonly used InputStream. The constructor takes a filename, File object or FileDescriptor as a parameter. Data read from this stream comes from the file identified in the constructor.
PipedInputStream	Connects to an Instance of PipedOutputStream. This provides a one-way stream through which two threads may communicate. Note: Threading hasn't been covered in this course yet.
March 25, 2009	Slides by Mark Hancock (adapted from notes by Craig Schock)

OutputStream methods

Method	Description
void write(int data)	Writes the data as a byte
void write(byte[] buffer)	Writes all of the bytes contained within the buffer to the stream
void write(byte[] buffer, int offset, int length)	writes <i>length</i> bytes to the stream starting at point buffer[offset]
void flush()	Flushes the OutputStream and forces any buffered output to be written to the stream
void close()	Closes the stream and releases any resources associated with the stream

March 25, 2009 Slides by Mark Hancock (adapted from notes by Craig Schock)

21

OutputStream subclasses

Class	Description
ByteArrayOutputStream	All bytes written to this stream will be stored in a byte array. This array can be recovered by using the toByteArray() method
FileOutputStream	Most commonly used OutputStream. The constructor takes a filename, File object or FileDescriptor object as a parameter. All bytes written to this stream will be written to the underlying file. Has constructors which indicate that new data written to the file should be appended to the end of the file.
ObjectOutputStream	The constructor for this stream takes another stream as a parameter. Programmers can serialize objects by writing them to this stream using the writeObject() method.
PipedOutputStream	Connects to an instance of PipedInputStream to provide a one-way communication stream through which 2 threads may communicate

March 25, 2009 Slides by Mark Hancock (adapted from notes by Craig Schock)

Limitations

- Good for ASCII encodings of characters
- Reading/writing unicode characters requires extra effort
 - e.g., internationalized character sets

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

23

Character Streams

- Unit being read or written is a (unicode) character
- Two important parent classes
 - Reader
 - Writer

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Does it make sense to read in some bytes as if they were characters?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

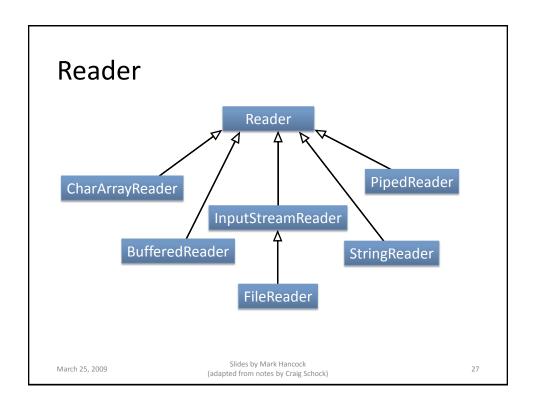

25

Conversion Classes

- InputStreamReader
 - converts an InputStream into a Reader
- OutputStreamWriter
 - converts an OutputStream into a Writer

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Method	Description
int read()	reads a character and returns it as an integer (only 16 bits are valid)
read (char[] buffer)	reads characters into the array up to the length of the array
read (char[] buffer, int offset, int length)	reads length characters into a character array starting at poing buffer[offset]
close()	closes the stream and releases any resources associated with the Reader
boolean ready()	returns true if the next call to read will not result in a block
boolean markSupported()	returns true if this Reader supports the mark() and reset() operations
mark(int readAheadLimit)	mark the present location in the stream.

resets the stream to the location previously set with mark()

Slides by Mark Hancock (adapted from notes by Craig Schock)

skips n characters in the stream

Reader methods

reset()

skip (long n)

March 25, 2009

Reader subclasses

March 25, 2009

Class	Description
PipedReader	Used to create a one-way pipe between threads. A PipedReader object represents the receiving side of the pipe
BufferedReader	Provides a mechanism for reading characters from an input source while buffering the characters so that more efficient reading can occurr
CharArrayReader	Similar to ByteArrayInputStream. Used so that a character array can provide the data for a Reader. This is useful if the programmer wishes to read from a Character Array using the stream interfaces.
StringReader	Similar to the CharArrayReader where the data source is a String object.
InputStreamReader	An InputStreamReader is a bridge from byte streams to character streams: It reads bytes and decodes them into characters using a specified character set.
FileReader	A convenience class for reading textfiles.

Slides by Mark Hancock (adapted from notes by Craig Schock)

Writer

CharArrayWriter

OutputStreamWriter

StringWriter

FileWriter

StringWriter

StringWriter

StringWriter

FileWriter

StringWriter

Writer methods

Method	Description
write(int c)	writes the character to the stream. Note that even though the parameter is an integer, only 16 bits are written to the stream
write(String s)	writes the String to the stream
write(char[] buffer)	writes the buffer to the stream
write (String s, int offset, int length)	write <i>length</i> characters from the specified String starting at the specified offset
flush()	forces any characters currently being buffered to be written to the stream
close()	closes the stream and releases any resources associated with the stream

March 25, 2009 Slides by Mark Hancock (adapted from notes by Craig Schock)

Writer subclasses

Class	Description
PipedWriter	Used in conjunction with PipedReader to create a one-way communication between two threads.
BufferedWriter	Writes text to a character-oriented stream while buffering characters to provide for efficiency
CharArrayWriter	Writes characters to a character array which can be recovered using the toCharArray() or toString() methods
FileWriter	Convenience class for writing character files (text)
StringWriter	Writes characters to a StringBuffer which can be recovered using the toString() method
OutputStreamWriter	Bridge class between character-oriented streams and byte- oriented streams

March 25, 2009 Slides by Mark Hancock (adapted from notes by Craig Schock)

Exercise: create a method that writes out the contents of an ArrayList<String> to a file using the FileWriter class.

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

3

Filter Streams

- Similar to pipes on the command line
 - the output of one stream is the input of another
 - each filter modifies the data in some manner

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Filter Streams

Class	Description
DataInputStream	read primitive data types from an underlying input stream
DataOutputStream	writes primitive data types to an underlying output stream
PushbackInputStream	Allows the ability to push read data back onto the stream
GZIPInputStream	reads compressed data in the GZIP format
GZIPOutputStream	writes compressed data to the GZIP format
ZipInputStream	reads compressed data in the Zip format
ZipOutputStream	writes compressed data to the Zip format
PushbackReader	Allows the ability to push read data back onto the reader

March 25, 2009 Slides by Mark Hancock (adapted from notes by Craig Schock)

Example

```
import java.io.*;
import java.util.zip.*;

public class CompressProgram
{
   public static void main(String[] args) throws IOException
   {
      File file = new File("zipped-text.zip");
      FileOutputStream fos = new FileOutputStream(file);
      ZipOutputStream zos = new ZipOutputStream(fos);
      OutputStreamWriter osw = new OutputStreamWriter(zos);
      BufferedWriter writer = new BufferedWriter(osw);

      zos.putNextEntry(new ZipEntry("text.txt"));

      writer.write("Line one");
      writer.newLine();
      writer.newLine();

      writer.newLine();

      writer.close();
   }
}

March 25, 2009

      Slides by Mark Hancock
   (adapted from notes by Craig Schock)

36
```

Discussion: How would you store an object that you created in a file (e.g., a Tag Cloud)?

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

3

Serializable interface

- An interface with no methods that flags any class as something that can be written to a file
- Use ObjectInputStream's readObject method and ObjectOutputStream's writeObject method to read/write objects

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

Example

```
public class TagCloud implements Serializable
{
    // Document must also implement Serializable
    private Document document;

    // ...
}
```

March 25, 2009

Slides by Mark Hancock (adapted from notes by Craig Schock)

39

Exercise: make this Serializable

```
public class PeriodicTable
{
   private HashMap<String, Atom> atomMap;
   // ...
}
```
